App.Archiyou

A high-fidelity design of the Archiyou workspace, designed to support project-based workflows. It shows how users manage scripts, design files, and shared resources while maintaining clarity between tools, results, and workspaces.

1. Overall Interaction Model V.1.0

The interaction model distinguishes between tools, results, and project context, while explicitly supporting reuse through community-shared scripts. Users can move between creating their own capabilities, applying shared resources, and managing project-based outputs, allowing individual work and community contribution to coexist within the same workflow.

Experience rationale

- Supports exploratory, project-based work and learning-by-doing
- Reduces cognitive load by clearly separating tools, results, and project context
- Aligns with parametric design mental models and reuse-driven workflows

The Home screen functions as a workspace overview, giving users immediate access to their active projects, reusable scripts, design files, and shared community resources.

Content is organized by intent rather than by technical structure: producing design files, creating scripts, reusing shared scripts, or managing project context.

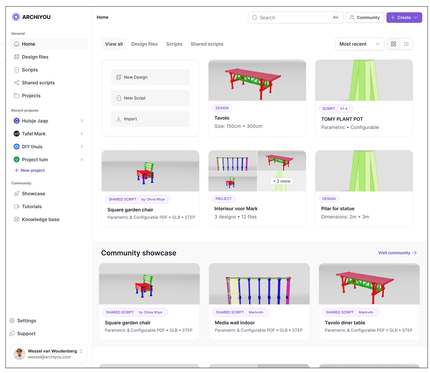
Each card explicitly communicates its object type (Design, Script, Shared Script, Project), allowing users to immediately understand whether they are looking at a result, a tool, a shared resource, or a workspace.

- Recognition over recall
- Prevents conceptual overlap

Design files emphasize tangible properties such as dimensions, reinforcing their role as finalized or shareable results rather than editable tools.

Projects aggregate multiple designs and files into a single workspace, visually communicating scope and progress rather than individual artifacts.

- Supports complex, multi-output work
- Aligns with real-world project organization



The high-level call to action provides a clear entry point for creation, allowing users to start a new project, create a design from a script, or begin with a standalone script.

Scripts highlight versioning and configurability instead of outputs, positioning them as reusable building blocks that can generate multiple design files.

Shared scripts are presented alongside personal content with clear author attribution, making community contributions discoverable without separating them from the core workflow.

The community showcase is visually separated from personal workspace content, positioning it as an inspiration and discovery layer rather than part of active work.

Projects

2. Project overview V.1.0

The project overview frames designs, scripts, and outputs within a shared project context, positioning the project as the primary unit of work rather than individual files.

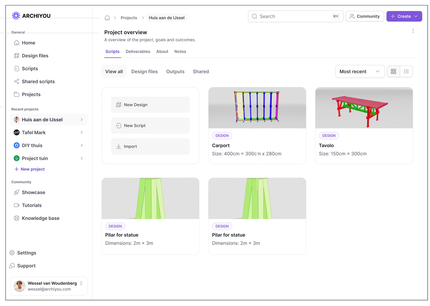
Experience rationale

- Supports long-running, iterative projects
- Reflects real-world design and construction workflows
- Enables multiple designs to coexist within a single context

Global navigation and project-specific context are kept visible at all times, ensuring users always understand where they are in the system.

Generated outputs remain attached to the project context, preserving traceability between configurations, designs, and results. This prevents loss of context between design and production, supports accountability and collaboration and enables revisiting earlier decisions

The interface explicitly separates tools (scripts), results (designs and outputs), and project context, reducing cognitive load and improving navigability.



Individual designs are presented as discrete, inspectable artifacts rather than anonymous files.

Design cards use consistent visual previews and metadata, supporting fast scanning and recognition across projects.

Script detail page

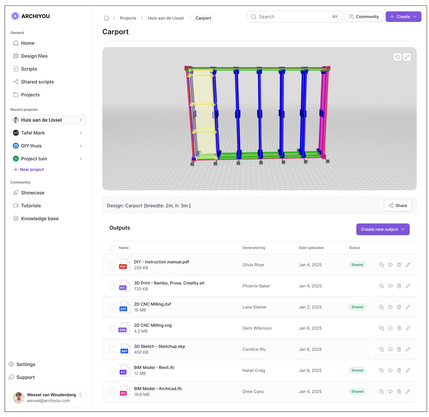
3. Script detail page V.1.0

The script detail page positions scripts as reusable capabilities that generate designs and outputs, rather than as isolated code artifacts. It supports reuse across projects and designs, makes capabilities explicit and inspectable and aligns with parametric and open design workflows.

Experience rationale

- Reduces cognitive overload
- Prevents confusion between source and output
- Supports predictable iteration

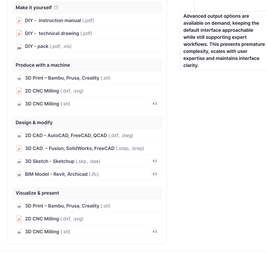
Breadcrumbs and persistent navigation make it clear how the script fits within the broader project and system structure.



The interface separates the script itself from the generated design and outputs, clarifying the distinction between the capability and its results.

The central 3D preview shows the current result of the script, providing immediate visual context without obscuring the script's role as the source.

Output options are presented alongside the script, allowing users to translate script results into concrete deliverables without leaving context.



Advanced output options are available on demand, keeping the default interface approachable while still supporting expert workflows. This prevents premature complexity, scales with user expertise and maintains interface clarity.

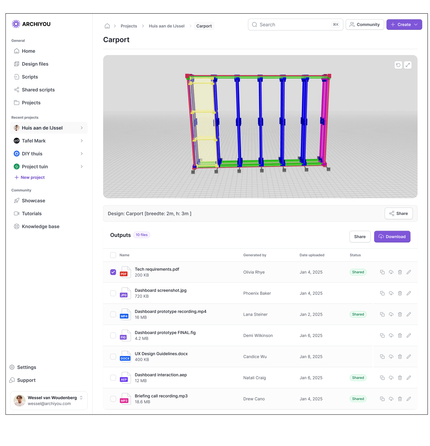
Project design file details

3. Managing scripts V.1.0

The managing scripts view treats scripts as maintainable capabilities within a project, rather than one-off tools or isolated code files.

Experience rationale

- Supports long-term project evolution
- Encourages reuse and iteration
- Aligns with parametric and capability-driven design systems



Primary actions focus on generating and managing outputs, while secondary actions support sharing and collaboration.

Generated outputs display ownership and sharing status, making collaboration explicit without introducing heavy coordination UI.
